MACHINE LEARNING (ML) Basics: CS5200

The goal of learning is prediction. Learning falls into many categories, including:

- Supervised learning,
- Unsupervised learning,
- Semi-supervised learning
- Transfer Learning
- Online learning, and
- Reinforcement learning
- Incremental Learning
- Deep Learning.

Supervised learning is best understood and studied.

Machine Learning is ...

an algorithm that can learn from data without relying on rules-based programming.

learning problems. Some major classes of learning problems are:

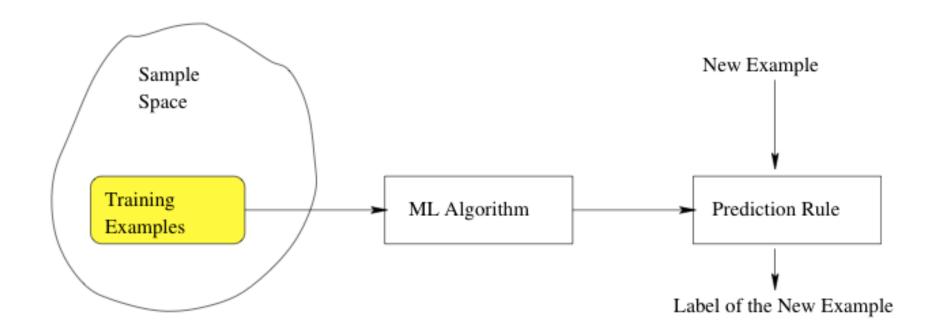

- Classification: Assign a category to each item. For example, document classification may assign items with categories such as politics, business, sports, or weather while image classification may assign items with categories such as landscape, portrait, or animal. The number of categories in such tasks is often relatively small, but can be large in some difficult tasks and even unbounded as in OCR, text classification, or speech recognition.
- Regression: Predict a real value for each item. Examples of regression include prediction of stock values or variations of economic variables. In this problem, the penalty for an incorrect prediction depends on the magnitude of the difference between the true and predicted values, in contrast with the classification problem, where there is typically no notion of closeness between various categories.
- Ranking: Order items according to some criterion. Web search, e.g., returning web pages relevant to a search query, is the canonical ranking example. Many other similar ranking problems arise in the context of the design of information extraction or natural language processing systems.
- Clustering: Partition items into homogeneous regions. Clustering is often performed to analyze very large data sets. For example, in the context of social network analysis, clustering algorithms attempt to identify "communities" within large groups of people.
- Dimensionality reduction or manifold learning: Transform an initial representation of items into a lower-dimensional representation of these items while preserving some properties of the initial representation. A common example involves preprocessing digital images in computer vision tasks.

In <u>supervised learning</u>, an algorithm is given samples that are labeled in some useful way. For example, the samples might be descriptions of apples, and the labels could be whether or not the apples are edible.

Supervised learning involves learning from a training set of data. Every point in the training is an input-output pair, where the input maps to an output. The learning problem consists of inferring the function that maps between the input and the output in a predictive fashion, such that the learned function can be used to predict output from future input.

The algorithm takes these previously labeled samples and uses them to induce a classifier. This classifier is a function that assigns labels to samples including the samples that have never been previously seen by the algorithm.

The goal of the supervised learning algorithm is to optimize some measure of performance such as minimizing the number of mistakes made on new samples.

Machine Learning is ...

a subfield of computer science and artificial intelligence which deals with building systems that can learn from data, instead of explicitly programmed instructions.

Unit 1 - Basics

Introduction to machine learning - different forms of learning; Basics of probability theory, linear algebra and optimization.

Unit 2 – Regression Analysis

Linear regression, ridge regression, Lasso, Bayesian regression, regression with basis functions.

• Unit 3 - Classification Methods

Linear Discriminant Analysis, Logistic regression, Perceptrons, Large margin classification, Kernel methods, Support Vector Machines, Classification and Regression Trees, Multilayer Perceptrons and Back propagation.

• Unit 4 - Graphical Models

Bayesian Belief Networks, Markov Random Fields, Exact inference methods, approximate inference methods.

• Unit 5 - Ensemble Methods

Boosting - Adaboost, Gradient Boosting; Bagging - Simple methods, Random Forest.

Unit 6 – Computational Learning Theory

PAC Learning, VC Dimension, Bias/Variance Tradeoff.

Unit 7 – Clustering

Partitional Clustering - k-means, k-medoids; Hierarchical Clustering - Agglomerative, Divisive, Distance measures; Density based clustering - DBScan; Spectral clustering

Unit 8 – Frequent Pattern Mining

Apriori Algorithm; FP-Growth

http://www.cse.iitm.ac.in/~vplab/E_machine_learning.html

- Examples: Items or instances of data used for learning or evaluation. In our spam problem, these examples correspond to the collection of email messages we will use for learning and testing.
- Features: The set of attributes, often represented as a vector, associated to an example. In the case of email messages, some relevant features may include the length of the message, the name of the sender, various characteristics of the header, the presence of certain keywords in the body of the message, and so on.
- Labels: Values or categories assigned to examples. In classification problems, examples are assigned specific categories, for instance, the SPAM and non-SPAM categories in our binary classification problem. In regression, items are assigned real-valued labels.
- Training sample: Examples used to train a learning algorithm. In our spam problem, the training sample consists of a set of email examples along with their associated labels. The training sample varies for different learning scenarios, as described in section 1.4.

- Validation sample: Examples used to tune the parameters of a learning algorithm when working with labeled data. Learning algorithms typically have one or more free parameters, and the validation sample is used to select appropriate values for these model parameters.
- Test sample: Examples used to evaluate the performance of a learning algorithm. The test sample is separate from the training and validation data and is not made available in the learning stage. In the spam problem, the test sample consists of a collection of email examples for which the learning algorithm must predict labels based on features. These predictions are then compared with the labels of the test sample to measure the performance of the algorithm.
- Loss function: A function that measures the difference, or loss, between a predicted label and a true label. Denoting the set of all labels as \mathcal{Y} and the set of possible predictions as \mathcal{Y}' , a loss function L is a mapping $L: \mathcal{Y} \times \mathcal{Y}' \to \mathbb{R}_+$. In most cases, $\mathcal{Y}' = \mathcal{Y}$ and the loss function is bounded, but these conditions do not always hold. Common examples of loss functions include the zero-one (or misclassification) loss defined over $\{-1,+1\} \times \{-1,+1\}$ by $L(y,y') = 1_{y'\neq y}$ and the squared loss defined over $I \times I$ by $L(y,y') = (y'-y)^2$, where $I \subseteq \mathbb{R}$ is typically a bounded interval.
- Hypothesis set: A set of functions mapping features (feature vectors) to the set of labels \mathcal{Y} . In our example, these may be a set of functions mapping email features to $\mathcal{Y} = \{\text{SPAM}, \text{non-SPAM}\}$. More generally, hypotheses may be functions mapping features to a different set \mathcal{Y}' . They could be linear functions mapping email feature vectors to real numbers interpreted as scores ($\mathcal{Y}' = \mathbb{R}$), with higher score values more indicative of SPAM than lower ones

Computational learning theory studies the time complexity and feasibility of learning. In computational learning theory, a computation is considered feasible if it can be done in polynomial time.

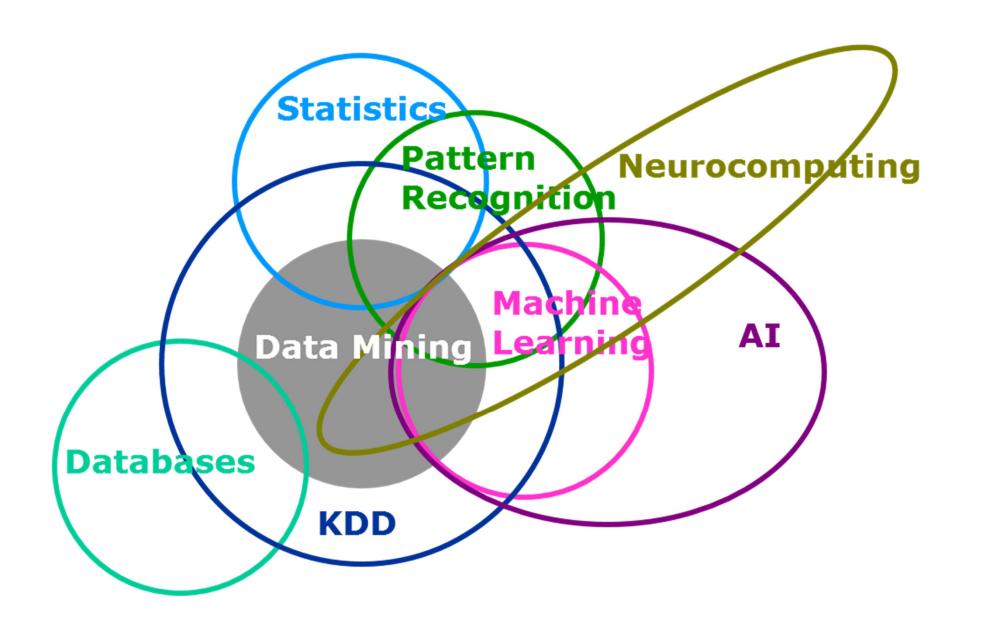

Classification problems are those for which the output will be an element from a discrete set of labels. Classification is very common for machine learning applications. The input would be represented by a large multidimensional vector whose elements represent pixels in the picture, say CV applications.

After learning a function based on the training set data, that function is validated on a test set of data, data that did not appear in the training set.

Computational learning theory

(Wikipedia)

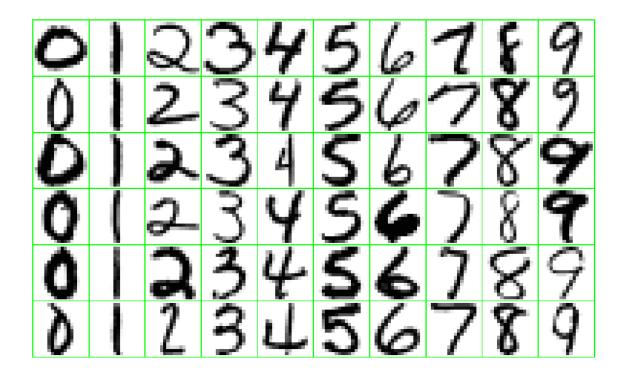

- **Probably approximately correct learning** (PAC learning) -- Leslie Valiant
 - inspired boosting
- VC theory -- Vladimir Vapnik
 - led to SVMs
- Bayesian inference -- Thomas Bayes
- Algorithmic learning theory -- E. M. Gold
- Online machine learning -- Nick Littlestone
- SRM (Structural risk minimization)
 - model estimation

Example: Recognition of Handwritten Digits

- Data: images are single digits 16x16 8-bit gray-scale, normalized for size and orientation
- Classify: newly written digits

- Non-binary classification problem
- Low tolerance to misclassifications

Categories of **Supervised Learning**:

- Linear Regression Prediction using Least Squares
- Function Approximation Linear basis expansion, cross entropy
- Bayes
- Regularization
- Kernel methods & SVM;
- Basis and Dictionary methods;
- Model selection
- Perceptron, ANN
- Bagging, Boosting, Additive Trees

- Logistic Regression, LDA
- Inductive Learning
- Decision Trees
- Deep Learning

Unsupervised Learning

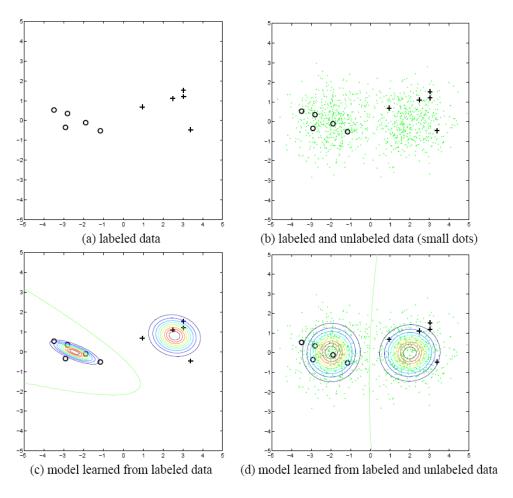

- No training data in the form of (input, output) pair is available
- Applications:
 - Dimensionality reduction
 - Data compression
 - Outlier detection
 - Classification
 - Segmentation/clustering
 - Probability density estimation

- ...

Semi-supervised Learning

- Uses both labeled data (in the form (input, output) pairs) and unlabelled data for learning
- When labeling of data is a costly affair semi-supervised techniques could be very useful
- Examples: Generative models, self-training, co-training

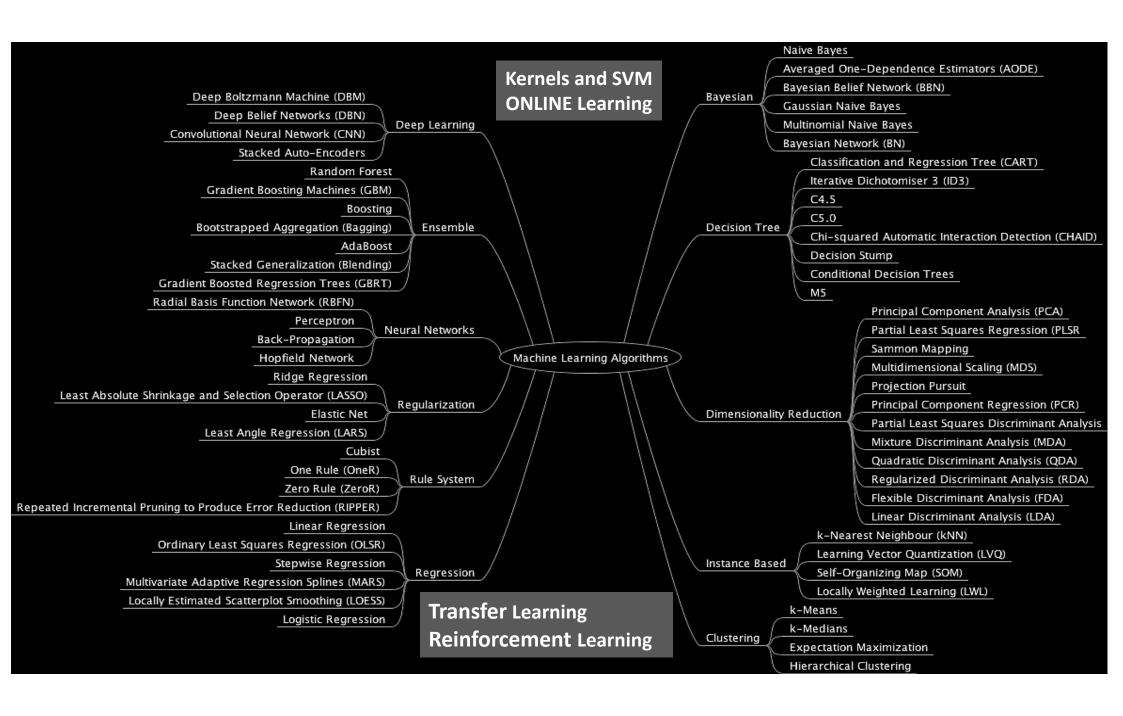

Example: Semi-supervised Learning

Source: Semi-supervised literature survey by X. Zhu, Technical Report

Reinforcement Learning

- Reinforcement learning is the problem faced by an agent that must learn behavior through trial-and-error interactions with a dynamic environment.
- There is no teacher telling the agent wrong or right
- There is critic that gives a reward / penalty for the agent's action
- Applications:
 - Robotics
 - Combinatorial search problems, such as games
 - Industrial manufacturing
 - Many others!

Applications:

- Document Classification and email SPAM filtering;
- Object Recognition + face, fingerprint, hand-writing, printed text (OCR), inpainting
- Action Classification in videos; Video surveillance, Self-driving cars
- Exit polls, Stock Market, Weather, Social media
- Identifying patterns/clusters/structures in big data
- Search Engines, market analysis, Robotics
- Matrix completion
- Virtual Assistance Alexa etc.
- Manufacturing; Quality Control, Customer support, product recommendations
- Health care, collaborative filtering, software/hardware design
- Agriculture

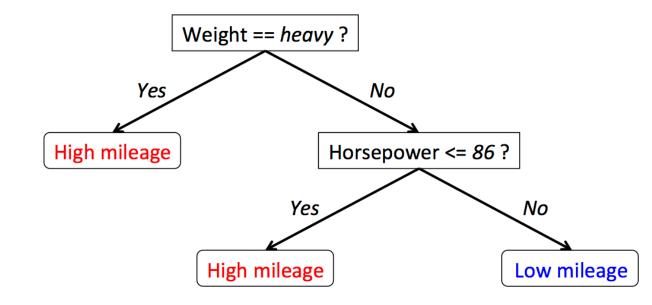

Decision trees

- One possible representation for hypotheses
- E.g., here is the "true" tree for deciding whether to wait:

Decision Tree Model for Car Mileage Prediction

ONLINE LEARNING (src: Wiki)

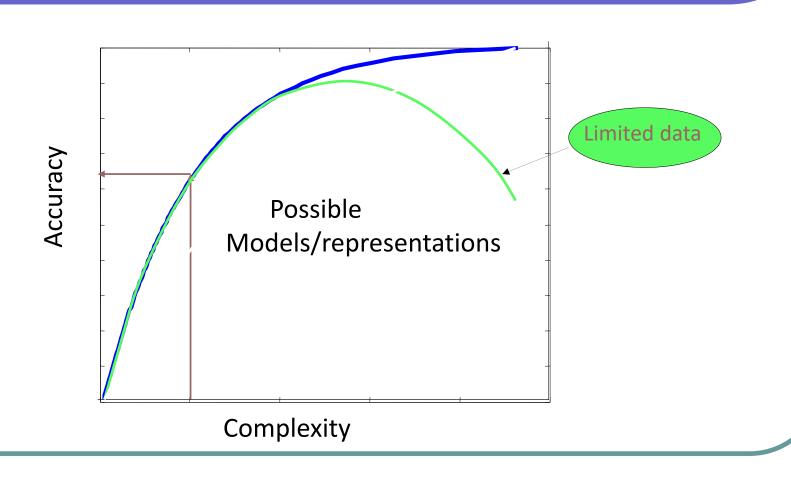

In Online machine learning data becomes available in a sequential order and is used to update our best predictor for future data at each step, as opposed to batch learning techniques which generate the best predictor by learning on the entire training data set at once.

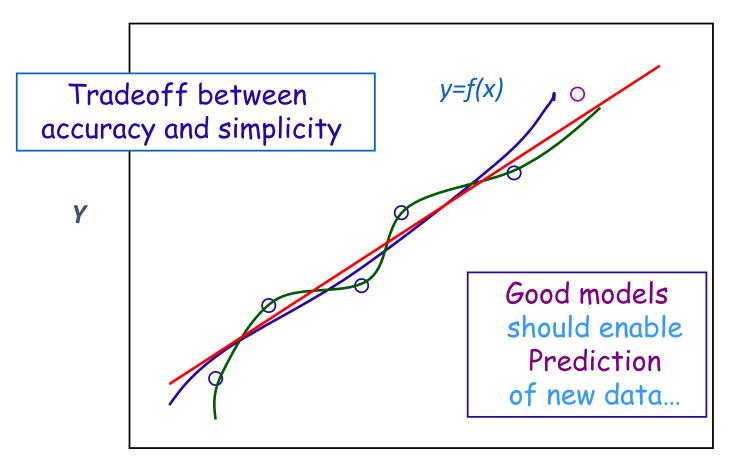

In this case, it is necessary for the algorithm to dynamically adapt to new patterns in the data, or when the data itself is generated as a function of time, e.g. stock price prediction. Online learning algorithms may be prone to catastrophic interference. This problem is tackled by incremental learning approaches.

A purely online model would learn based on just the new input, the current best predictor and some extra stored information (which is usually expected to have storage requirements independent of training data size).

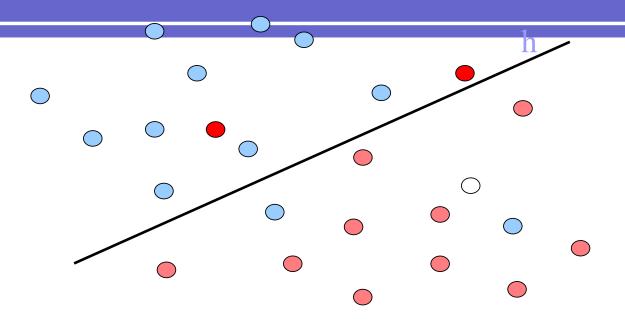

A common strategy to overcome the issue of storage, is to learn using minibatches, which process a small batch of data points at a time, this can be considered as pseudo-online learning for much smaller than the total number of training points.

A Fundamental Dilemma of Science: Model Complexity vs Prediction Accuracy

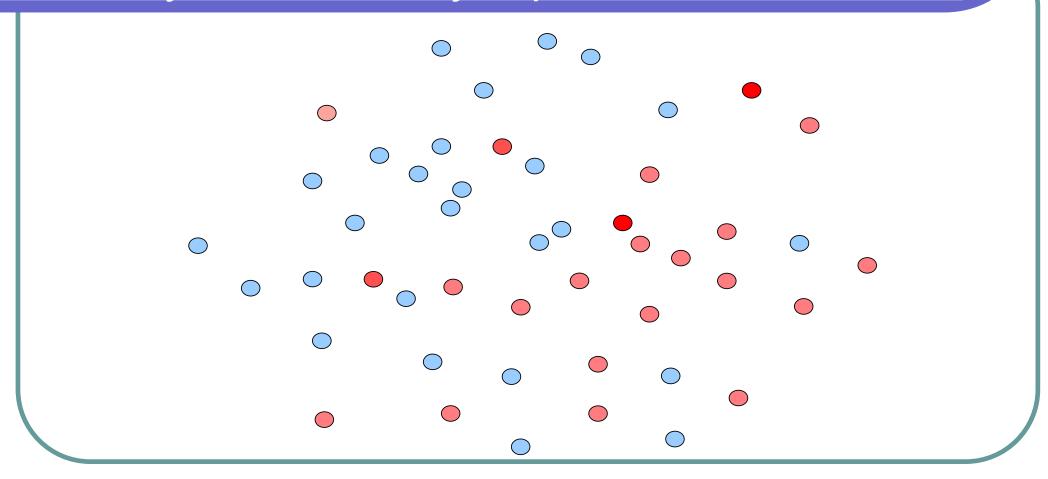

Concrete learning paradigm- linear separators

The predictor h: Sign ($\mathbb{P} w_i x_i + b$)

(where w is the weight vector of the hyperplane h, and $\mathbf{x}=(\mathbf{x}_1, \dots \mathbf{x}_i, \dots \mathbf{x}_n)$ is the example to classify)

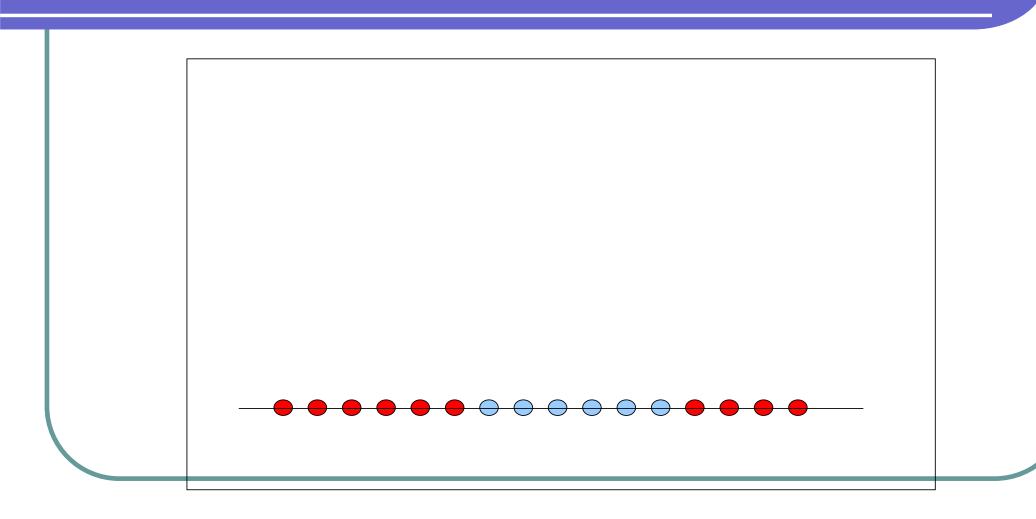

Potential problem – data may not be *linearly separable*

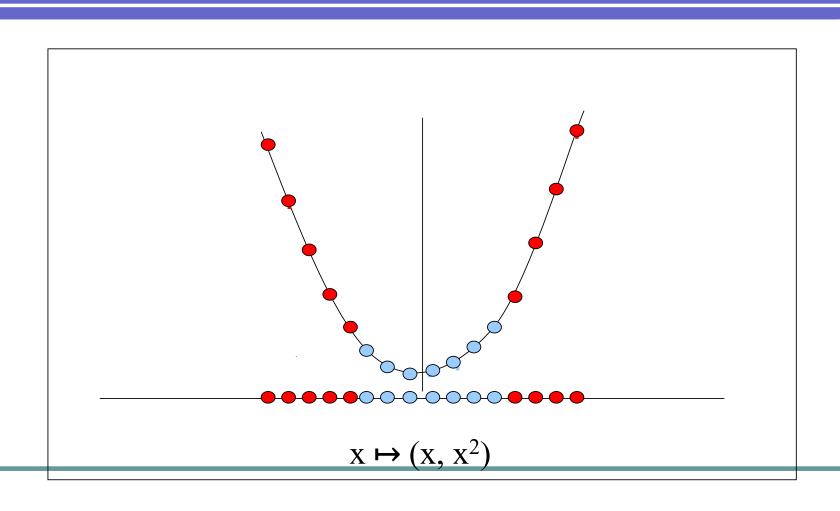

The SVM Paradigm

- Choose an Embedding of the domain X into some high dimensional Euclidean space, so that the data sample becomes (almost) linearly separable.
- Find a large-margin data-separating hyperplane in this image space, and use it for prediction.

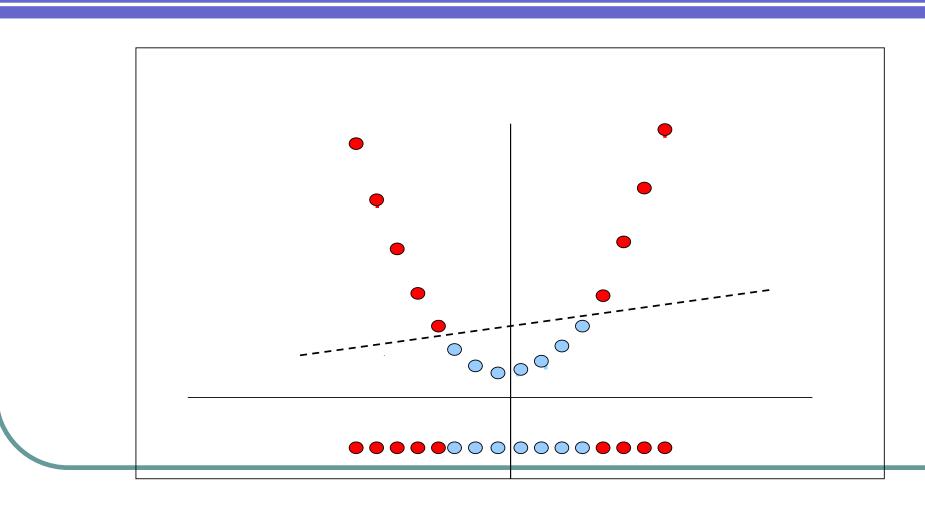

The SVM Idea: an Example

The SVM Idea: an Example

The SVM Idea: an Example

Controlling Computational Complexity

Potentially the embeddings may require very high Euclidean dimension.

How can we search for hyperplanes efficiently?

The Kernel Trick: Use algorithms that depend only on the inner product of sample points.

Kernel-Based Algorithms

Rather than define the embedding explicitly, define just the matrix of the inner products in the range space.

$$\begin{bmatrix} K(x_1x_1) & K(x_1x_2) & \dots & K(x_1x_m) \\ \vdots & K(x_ix_j) & \vdots \\ \vdots & \vdots & \vdots \\ K(x_mx_1) & \dots & K(x_mx_m) \end{bmatrix}$$

Mercer Theorem: If the matrix is symmetric and positive semi-definite, then it is the inner product matrix with respect to some embedding

Support Vector Machines (SVMs)

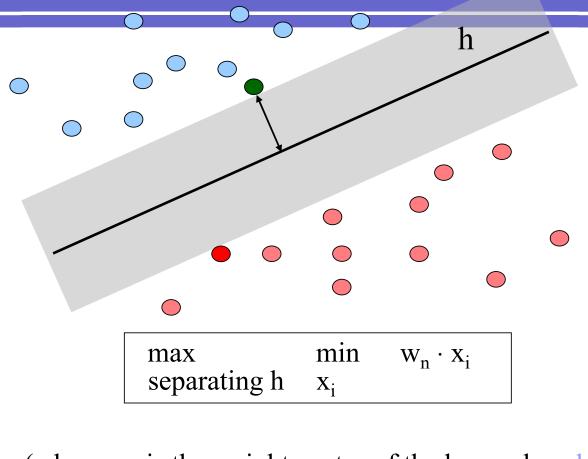

On input: Sample $(x_1 y_1) \dots (x_m y_m)$ and a

kernel matrix K

Output: A "good" separating

hyperplane

The Margins of a Sample

(where w_n is the weight vector of the hyperplane h)

Summary of SVM learning

- 1. The user chooses a "Kernel Matrix"
 - a measure of similarity between input points.
- Upon viewing the training data, the algorithm finds a linear separator the maximizes the margins (in the high dimensional "Feature Space").

- Model Selection;
- Online Learning
- Curse of Dimensionality
- Bias-Variance Tradeoff
- Transfer Learning Domain Adaptation
- BOW, Sparse Coding
- Incremental Learning
